## PROCESS FOR CONTROLLING THE PARTICLE SIZE IN A BAYER CIRCUIT PRECIPITATION SYSTEM, INCLUDING AN AGGLOMERATION PHASE

## ABSTRACT OF THE DISCLOSURE

Control over the precipitation of an American type BAYER circuit in which the particle size quality of the hydrate produced is monitored by making a measurement of the amount of rotating hydrate passing X2  $\mu\text{m}$ , comprising:

- a) a preparation step intended to setup a relation R between the material passing X1 μm and material passing X2 μm, where X1 is less than X2, and then use R to deduce trigger thresholds on the amount of material passing X1 μm;
- b) control of the process itself which, apart from the daily measurement of material passing X2 µm, includes a daily measurement of the rotating hydrate passing X1 µm and triggering of a corrective action in the slurry at the beginning of precipitation when the measured value of material passing X1 µm reaches one of the regularly updated trigger thresholds determined in the previous step.
